(54) Title: DISPLAY DEVICE

(57) Abstract: Display device based on layer break up or layer displacement having at least two different states, in which one of the fluids (5) e. g. oil in a first state adjoins at least a first support plate (3) and in the second state the other fluid (6) at least partly adjoins the first support plate. In one embodiment a picture element corresponds to a substantially closed space and in the first state the other fluid layer substantially completely adjoins both support plates and is divided in two sub-layers. This makes it possible on the one hand to use lower voltages to make displacement occur. On the other hand this opens the opportunity to color displays.

Eurasian patent (AM, AZ, BY, KG, KZ, MD, RU, TJ, TM),
European patent (AT, BE, BG, CH, CY, CZ, DE, DK, EE,

Display device

The invention relates to a display device comprising picture elements having at least one first fluid and a second fluid immiscible with each other within a space between a first support plate and a second support plate, one of the fluids being electroconductive or polar, the device comprising means for creating at least two different states.

5 The invention further relates to a switchable diffusing device.

Display devices like TFT-LCDs are used in laptop computers and in organizers, but also find an increasingly wider application in GSM telephones. Instead of LCDs, for example, (polymer) LED display devices are also being used.

10 Apart from these display effects which are well established by now other display techniques are evolving like electrophoretic displays, which are suitable for paper white applications.

The diffusing device may be used in several devices such as cameras.

15 The display device according to the invention has at least two different states, in which one of the fluids in a first state adjoins at least the first support plate and in the second state the other fluid at least partly adjoins the first support plate.

The invention is based on a principle discovered by the inventors so called layer break up, but on the other hand layer displacement may be used. The invention provides
20 new ways of using these principles.

If for instance a (first) fluid is a (colored) oil and the second (the other) fluid is water (due to interfacial tensions) a two layer system is provided which comprises a water layer on top of the oil layer. However, if a voltage is applied between the two layers the oil layer breaks up due to electrostatic forces. Since parts of the water now penetrate the oil layer
25 the picture element becomes partly transparent.

The contrast is limited by the fraction of area occupied by the droplets of the (first) fluid ((colored) oil) remaining after the break-up. Typically, depending on the thickness of the original fluid layer an area of 25 – 50 % is realized. This can be decreased further by applying higher voltages, which however would increase the dissipated power

significantly. Ideally, one would like the remnant area occupied by the fluid, in this case optically absorbing oil, to approach 0%.

A further limitation is that, upon break-up, the area fraction is reduced instantly to about 50%. It is therefore hard to obtain area fractions close to 100 %. As a result
5 realizing of analog gray scales may become difficult.

In a first embodiment a picture element corresponds to a defined space (e.g. a substantially closed space) and in the second state the other fluid substantially completely adjoins the first support plate. According to a further aspect of the invention this is achieved by applying an inhomogeneous electric field. In that case the threshold field for layer break up
10 (or displacement) will be exceeded only at certain specific places. At those places oil-film break up (or displacement) will be initiated. An inhomogeneous applied electric field can be obtained in several ways.

To this end in a first preferred embodiment of the invention the dielectric layer between an electrode and the surface of the part of the first support plate varies in thickness.

15 In a further embodiment the dielectric layer between an electrode and the surface of the part of the first support plate has a varying dielectric constant.

By increasing the electric field the threshold for oil-film break up (or displacement) is displaced over the area of the support plate and can be controlled. This makes possible the realization of grey levels.

20 On the other hand oil-film break up (or displacement) can be controlled by varying the wettability of the part of the first support plate or the thickness of the first fluid layer.

Furthermore it is possible to use the stray field distribution at the edge of electrodes, or even design a segmented electrode structure that provides the desired
25 inhomogeneous field distribution.

In a further embodiment according to the invention a picture element corresponds to a defined space and in the first state the other fluid layer substantially completely adjoins both support plates. In fact the other fluid layer (the oil layer) is now divided in two sub-layers, which each may be thinner. This makes it possible on the one hand
30 to use lower voltages to make oil-film break up (or displacement) occur. On the other hand this opens the opportunity to color displays and the realizing of a larger variety of gray-values.

To this end in a preferential embodiment of the invention a picture element corresponds to a defined space having a further wall dividing the space into at least two sub-

picture elements, in the first state a further other fluid layer adjoining the first support plate at least partly within the sub-picture elements. By giving said (further) other fluid layer different colors a color display is obtained.

To obtain a remnant area occupied by the further fluid after break up in the
5 second state at least one of the other fluid layer and the further other fluid layer adjoins a wall of the space. To prevent intermixing of the material of both sub-layers adjoining the wall the device preferably comprises means to prevent part of the other fluid layer and the further other fluid layer to intermix in the second state.

These and other aspects of the invention are apparent from and will be
10 elucidated with reference to the embodiments described hereinafter.

In the drawings:

Fig. 1 is a diagrammatic cross-section of a part of a display device according
15 to the invention,

Fig. 2 is another diagrammatic cross-section of a part of a display device according to the invention,

Fig. 3 is a diagrammatic of a part of a display device according to the invention

20 Fig. 4 is a diagrammatic cross-section of a part of a color display device according to the invention, while

Figures 5, 6 and 7 show further embodiments of the invention and

Figure 8 shows another diagrammatic cross-section of a part of a display device according to the invention

25 The Figures are diagrammatic and not drawn to scale. Corresponding elements are generally denoted by the same reference numerals.

Fig. 1 shows a diagrammatic cross-section of a part of a display device 1
30 according to the invention. Between two transparent substrates or support plates 3, 4 a first fluid 5 and a second fluid 6 are provided, which are immiscible with each other. The first fluid 5 is for instance an alkane like hexadecane or as in this example a (silicone) oil. The second fluid 6 is electroconductive or polar, for instance water or a salt solution (e.g. a solution of KCl in a mixture of water and ethyl alcohol). In a first state, when no external

voltage is applied (Fig. 1a) the fluids 5, 6 adjoin the first and second transparent support plates 3, 4 of e.g. glass or plastic. On the first support plate 3 a transparent electrode 7, for example indium (tin) oxide is provided and an intermediate hydrophobic layer 8, in this example an amorphous fluoropolymer (AF1600).

5 The inventors have found that when a voltage is applied (voltage source 9) the layer 5 breaks up into small droplets (Fig. 1b, fragmented film). Break-up occurs when the electrical energy gain is larger than the surface energy loss due to the creation of curved surfaces. As a very important aspect it was found that reversible switching between a continuous film and a fragmented film is achieved by means of the electrical switching
10 means (voltage source 9).

This effect can be used for electro - optical effects, especially if a colored oil is used a display effect. This is achieved with an optically active oil, for example an opaque or reflective oil. In other embodiments a fluid with optically active particles is used or a dye material is dissolved in the oil. The electro - optical effect may either be used in a transparent
15 way, by using a back light, as for instance known from LCD technology or in a reflective way by using a (diffusive) reflector.

The droplet size depends on the voltage applied, which in principle offers the possibility of introducing intermediate transmission (or reflection) states (gray levels). However it was also found that, upon break-up, the area fraction is reduced practically
20 instantly to about 50%. It is therefore hard to obtain area fractions between 50% and 100 %. As a result, arbitrary analog gray scales in this particular range are difficult to be realized.

On the other hand the contrast is limited by the fraction of area occupied by the droplets resulting after the break-up. At practical voltages (in view of driving the display with IC drivers) see a minimal area fraction of about 25 % is observed. This can be decreased
25 further by applying higher voltages which, however, would increase the dissipated power significantly and possibly preclude the use of low voltage IC drivers.

To this end in the embodiment of Figure 2 the intermediate hydrophobic layers 8 have a curved form with the smallest thickness in the center, ensuring that the electrical field is highest in the center of a picture element 2. In this case the field varies in a radial
30 manner (by the varying thickness of the insulator). The threshold field will be first exceeded at the center of the pixel, where the insulator has the minimum thickness. Upon increasing the field, the position at which the applied field equals the threshold field will move outward, hence moving the oil to the side of the pixel. The schematic drawing in Figure 3 shows a cross-section of a pixel that is either circularly symmetric, or has a rectangular shape. In the

first case the oil will be pushed outward in a ring-like shape, starting from a single point in the center of the pixel. For a rectangular pixel one can envisage a insulator shaped like a slice of cylinder so that the oil break-up will start along a line, and the oil is pushed out in a curtain-like fashion.

5 By introducing this curved form of the layer 8 the optically absorbing oil layer 5 is displaced to a position inside the pixel, where the optical activity is no longer relevant, in this case to the side (or the back) of the pixel. Below a particular threshold field E_t no break-up occurs, whereas at fields higher than E_t the oil film will break-up into droplets. Break up was found to occur at field strengths of about $3\text{V}/\mu\text{m}$ over a wide range of insulator
10 thicknesses ($0.3 - 10\mu\text{m}$).

In another example the stray field distribution at the edge of electrodes is used, or a special electrode structure (segmented, perforated) that provides the desired inhomogeneous field distribution is used.

15 Although in this example oil break up has been considered, similar arguments apply to a device base on fluid displacement. On the other hand an inhomogeneous oil layer (due to e.g. insufficient volume, thickness variation or contact angles) may initiate the oil displacements (or break up).

In the case of oil-film break up for thick oil films 5 the oil film thickness is no longer negligible compared to the thickness of the insulator 8 and higher voltages are needed
20 to obtain oil film break up. Therefore, this principle is limited to the use of thin films (up till about 300 nm). For films of such thickness it is difficult to have sufficient optical absorption, which yields a reduced optical contrast between the on and off state.

In the case of displacement an inhomogeneous field distribution, that effectively gives rise to a varying surface tension across the pixel, is used. Now, the total
25 system can lower its energy by moving the oil to the position(s) with the lowest surface energy and one is able to move the oil film out of sight. This principle works at relatively low voltages for thicker oil films as well as thin ones, which relaxes the requirements for the optical absorptivity of the oil film. Furthermore this principle allows the realizing of gray values.

30 A further embodiment is shown in Figure 4 which comprises two separate oil layers 5, 5' on either side of the fluid (water) 6.

By either fabricating the pixel walls 13 out of a different material than the material of the layers 8, 8' (e.g. Teflon like AF 1600) or providing these walls 13 with such material 14 with a sufficiently high surface energy such that:

$$\gamma_{H_2O,S} < \gamma_{oil,H_2O} + \gamma_{oil,S}$$

(S indicates the solid barrier material 14) no oil film forms on the barriers or material 14.

- 5 This means that the upper oil film 5' and the lower oil film 5 are in no way connected to one another in either the first or the second state. Each layer can now be switched independently by contacting the water 6 by means of a through-connection (electrode 12 in Figure 4) through the upper (or lower) AF1600 layer. In practice this can be done by grounding the water 6 by means of electrode 12 and applying a voltage to either electrode 7 or electrode 11.
- 10 The device further comprises a diffuse white reflector 15. The viewing direction is indicated in Figure 4 by the arrows 16.

Some examples of materials for which the inequality given above holds are parylene, PMMA (polymethylmethacrylate) and glass.

- By giving the layers 5, 5' different colors, e.g. by introducing a dye, color displays are realized. This will be elucidated in the next examples.
- 15

Example 1 – Three color display

- In the embodiment of Figure 5 the oils 5 have different colors by using different dyes to realize a color display. In this example three kinds of e.g. oil are used, viz a red layer 5R, a green layer 5G and a blue layer 5B, to obtain the highest possible brightness for the configuration shown in Figure 5. A single pixel comprises a black absorber 16 (background) and two sub-pixels A and B, each having a configuration comparable to the one shown in Figure 4. The oil layer 5B on the top in the first state covers half of each of the sub-pixels. This can be achieved by locally modifying the surface energy of the layer 8' (AF1600). The other fluid, in this case water is assumed to be at a fixed voltage, for example ground (0V) via electrode 12.
- 20
- 25

- To obtain a red colored pixel in this configuration electrode 17 underneath the red layer of oil 5R should be grounded (0V) whereas electrode 18 underneath the green layer of oil 5G and electrode 11 above the blue layer of oil 5B should be activated by applying a voltage V. The green and blue layers will break up or move to the side and the sub-pixel B above the black absorber 16 becomes transparent. As a result, the total pixel will appear red, since sub-pixel A looks red and sub-pixel B looks black. The maximum brightness is limited to 50%. This maximum brightness is a significant improvement with respect to a configuration with 3 parallel pixels, where the maximum brightness is limited to 33%.
- 30

In a similar fashion, one can obtain a green pixel with a maximum brightness of 50% and a blue pixel with a maximum brightness of 50%. A summary of the voltages applied to the electrodes and the maximum brightness for each of the primary colors, black and white is given in Table 1.

5

color	voltage electrode 12	voltage electrode 17	voltage electrode 18	voltage electrode 11	brightness (%)
red	0	0	V	V	50
green	0	V	0	V	50
blue	0	V	V	0	50
white	0	0	0	0	varying
black	0	V	V	V	0

Table 1

The white state is obtained by reflecting light of all colored layers simultaneously. The color distribution of the white state however depends strongly on the size chosen for the blue layer 5B. In the example above, the blue layer occupies half of the pixel. As a result, the green and the red will contribute 25% to the white, which will seem distorted. If the blue layer covers 33% of the total area, the color distribution of the white state will look better, albeit with a low overall reflectivity of 33%. However, now the blue state will reach a maximum brightness of 33% instead of 50%.

15

The configuration as shown in Figure 5 is chosen as an example. Other configurations, with red or green on top can be used as well. In fact, by choosing the color with the highest reflectivity on top, one can reduce the color distortion caused by the different sizes of the area occupied by each of the colors and/or account for the eye sensitivity.

20

Example 2 – Three color plus white display

The variation in brightness in the white state arising in Example 1 can be circumvented by using a white oil. A white oil is e.g. obtained by dispersing scattering particles in the oil.

25

The configuration shown in figure 6 uses such a white oil. In a similar way as in Example 1 different colors are obtained by providing voltages to electrodes 17 (underneath the red layers of oil 5R), the electrodes 18 (underneath the green layers of oil 5G), the

electrodes 19 (above the blue layer of oil 5B) and the electrodes 20 (above the white layer of oil 5W). The result is given in Table 2.

color	voltage electrode 12	voltage electrode 17	voltage electrode 18	voltage electr. 19	voltage electr. 20	brightness (%)
red	0	0	V	V	V	50
green	0	V	0	V	V	50
blue	0	V	V	0	V	50
white	0	V	V	V	0	50
black	0	V	V	V	V	0

5

Table 2

As in the previous example, the color ordering can be altered if necessary. Also for example a high brightness white state, reflecting 100% can be achieved when the black absorber 16 is replaced by a white reflector and the oil layer at the top of sub-pixel B is black. However, in this configuration, no satisfactory black state can be obtained, due to the contribution of sub-pixel A which is either in a colored or a white state. This however reduces the contrast obtained.

Example 3 – Subtractive color display

Alternatively as shown in Figure 7 subtractive colors may be used. If two oil-layers 5 inside each sub-pixel are used one primary color per sub-pixel can be achieved. If a fixed subtractive color filter 21 is provided on top, a major improvement of the display performance is obtained. The pixel shown in Figure 7 consists of three sub-pixels A, B and C. In each of the sub-pixels the order of the subtractive colors alternates, i.e. M(agenta), C(yan), Y(ellow) for sub-pixel A, C(yan), Y(ellow), M(agenta), for sub-pixel B and Y(ellow), M(agenta), C(yan) for sub-pixel C.

It is now possible to make each of the primary colors in at least two of the sub-pixels. For instance in sub-pixel A, the magenta color filter part 21M absorbs green and the (switchable) yellow bottom oil layer 5Y absorbs blue. If the top cyan oil layer 5C, which absorbs red is switched to a transparent state, the red light is reflected by the white background layer (reflector 22) and sub-pixel A will appear red.

- In a similar way sub-pixel C will appear red by switching the bottom oil layer 5C to a transparent state. For sub-pixel B, the cyan color filter 21 C absorbs red and if none of the oil layers 5Y, 5M in B are switched to the transparent state will the sub-pixel B will appear black. Since the sub-pixels are sufficiently small the human eye does not distinguish the individual responses and the total pixel will appear red with a maximum brightness of 67%. Other colors can be obtained in a similar fashion. A summary of the colors and the corresponding voltage states are given in Table 3.

	Voltages on electrodes							
Color	electr.12	electr.32	electr.33	electr.34	electr.35	electr.36	electr.37	brigt (%)
red	0	0	0	V	V	0	0	67
green	0	0	V	0	0	0	V	67
blue	0	V	0	0	0	V	0	67
white	0	V	V	V	V	V	V	67
black	0	0	0	0	0	0	0	0

10

Table 3

- The protective scope of the invention is not limited to the embodiments described. For instance the layer 6 may be chosen to be scattering (by using a solution of TiO_2) or reflective (by using a solution of a suitable pigment). Driving voltages may also be capacitively coupled to the electrodes; especially capacitive coupling to electrodes 12 prevents degradation of the fluid 5. One or more reservoirs may be incorporated for overflow or supply of fluid(s) if fluid volumes in the reservoirs change due to temperature, pressure or otherwise.

- Figure 8 finally shows an embodiment in which the pixel walls 13 do not extend across the whole pixel thickness. It appears that the oil film 5 is very stable, which is enhanced even further as the pixel size decreases. So during switching the oil remains confined in each area providing the wall is not less than twice the height of the off-state oil film thickness. This means that a common channel can be employed for the fluid 6, which simplifies display fabrication and driving. The single electrical contact to the liquid can then be made externally. The other reference numerals have the same meaning as those in Figure 4.

The invention resides in each and every novel characteristic feature and each and every combination of characteristic features. Reference numerals in the claims do not limit their protective scope. Use of the verb "to comprise" and its conjugations does not exclude the presence of elements other than those stated in the claims. Use of the article "a" or "an" preceding an element does not exclude the presence of a plurality of such elements.

CLAIMS:

1. A display device comprising picture elements having a first fluid and at least one second fluid immiscible with each other within a space between a first support plate and a second support plate, the first fluid being electroconductive or polar, the device comprising means for creating at least two different states, in which one of the fluids in a first state
5 adjoins at least the first support plate and in the second state the other fluid at least partly adjoins the first support plate.
2. A display device according to Claim 1 in which a picture element corresponds to a defined space and in the second state the other fluid substantially completely adjoins the
10 first support plate.
3. A display device according to Claim 1 or 2, the device comprising means for creating within a picture element an inhomogeneous electric field at the surface of the part of
15 the first support plate.
4. A display device according to Claim 3 in which a dielectric layer between an electrode and a surface layer of the part of the first support plate varies in thickness.
5. A display device according to Claim 3 in which a dielectric layer between an
20 electrode and the surface of the part of the first support plate has a varying dielectric constant.
6. A display device according to Claim 1 or 2, the device within a picture element having a varying wettability at the surface of the part of the first support plate or a
25 varying thickness of the first fluid layer.
7. A display device according to Claim 1 in which a picture element corresponds to a defined space and in the first state a first fluid layer substantially completely adjoins both support plates.

8. A display device according to Claim 1 in which a picture element corresponds to a defined space having a wall part dividing the space into at least two sub-picture elements, in the first state a further fluid layer adjoining the first support plate at least partly within both sub-picture elements.
9. A display device according to Claim 8 in which the first fluid layer and the further fluid layer have different colors.
10. A display device according to Claims 2, 7 or 8 in which in the second state at least one of the first fluid layer and the further fluid layer adjoins a wall part of the space.
11. A display device according to Claim 10 which comprises means to prevent part of the first fluid layer and the further fluid layer to intermix in the second state.
12. A display device according to Claim 1 which comprises driving means to obtain intermediate states.
13. A display device according to Claim 1 which comprises an absorber or a reflector at the side of the first substrate.
14. A display device according to Claims 2, 7 or 8 in which the other layer is a scattering or an absorbing layer.
15. A display device according to Claims 2, 7 or 8 in which the other layer is common to several picture elements.
16. A display device according to Claim 1 which comprises a color filter.
17. A diffusing device having a first fluid and at least one second fluid immiscible with each other and confined in a space between a first support plate and a second support plate, the first fluid being electroconductive or polar, the device comprising means for creating at least two different states, in which one of the fluids in a first state adjoins at least

the first support plate and in the second state the other fluid at least partly adjoins the first support plate.
